In mathematics, deformation theory is the study of infinitesimal conditions associated with varying a solution P of a problem to slightly different solutions P', where  $\epsilon$  is a small number, or vector of small quantities. The infinitesimal conditions are therefore the result of applying the approach of differential calculus to solving a problem with constraints. One might think, in analogy, of a structure that is not completely rigid, and that deforms slightly to accommodate forces applied ...

Intuitively, a deformation of a scheme is a continuous family of schemes passing through our given scheme. One way to formalize this is to study morphisms of schemes  $E \rightarrow Y$  such that  $X = \epsilon^{-1}(p)$  for some  $k$ -point  $p$  of  $Y$ . In other words, the  $\epsilon$ -bers of  $\epsilon$  give us a family of schemes including  $X$  which is parametrized by  $Y$ .

In the deformation theory of VMO (see Cernocky and Kremp1, 1979, 1980 ), the equilibrium stress depends only on strain. As a consequence, the equilibrium stress did not change during relaxation and relaxation terminated at the equilibrium stress after infinite time. This property is also shared by the theory of Korzen (see Korzen, 1988; Haupt and Lion, 1995 ).

The basic problem of deformation theory in algebraic geometry involves watching a small deformation of one member of a family of objects, such as varieties, or subschemes in a fixed space, or vector bundles on a fixed scheme.

Deformation theory studies problems of extending structures to extensions of their domains. Formal deformation theory, is the part of the deformation theory where the extensions are infinitesimal. A typical problem in formal deformation theory has the structure that a morphism  $f: X \rightarrow Y$  of certain space  $s$  is given.

Deformation theory in nLab

The theory of deformations originated with the problem of classification of all possible pairwise non-isomorphic complex structures on a given differentiable real manifold. The fundamental idea (which must be credited to B. Riemann) was to introduce an analytic structure on the set of all such structures.

In physics, deformation is the continuum mechanics transformation of a body from a reference configuration to a current configuration. A configuration is a set containing the positions of all particles of the body. A deformation may be caused by external loads, body forces, or changes in temperature, moisture content, or chemical reactions, etc. Strain is a description of deformation in terms of relative displacement of particles in the body that excludes rigid-body motions. Different equivalent

For deformation theory in algebraic geometry, try taking a look at "Moduli of Curves" by Harris-Morrison, "Deformations of Algebraic Schemes" by Sernesi, or these notesof Hartshorne. One motivation to look at deformations comes from physics, see for example Kontsevich's famous paper on deformation quantization of Poisson manifolds.
