Graph database - Wikipedia
Graph Databases are described as databases that operate over graphs and where relationships between things matter. A graph is a type of structure and the underlying graph of a graph database maps the structure, or schema, of the data stored in the database.

Graph Databases, published by O'Reilly Media
A graph database is a specialized, single-purpose platform for creating and manipulating graphs. Graphs contain nodes, edges, and properties, all of which are used to represent and store data in a way that relational databases are not equipped to do.

The 7 Best Graph Databases to Consider for 2020
The ever increasing data volume and complexity is a serious problem, and that is precisely why graph databases were introduced. Bear with me as we learn what a graph database is. Data models. In order to understand how graph databases operate, we have to first go over the data models a little bit.

Introduction to graph databases | STEPWISE
Very simply, a graph database is a database designed to treat the relationships between data as equally important to the data itself. It is intended to hold data without constricting it to a pre-defined model. Instead, the data is stored like we first draw it out - showing how each individual entity connects with or is related to others.

What is a Graph Database? - Neo4j Graph Database Platform
Graph databases are purpose-built to store and navigate relationships. Relationships are first-class citizens in graph databases, and most of the value of graph databases is derived from these relationships. Graph databases use nodes to store data entities, and edges to store relationships between entities.

What Is a Graph Database?
A graph database is based on graph theory, uses nodes, properties, and edges and provides index-free adjacency. These database uses graph structures with nodes, edges, and properties to represent and store data. Every element contains a direct pointer to its adjacent elements and no index lookups are necessary in a graph database.

Graph databases, like Amazon Neptune, are purpose-built to store and navigate relationships. They have advantages over relational databases for use cases like social networking, recommendation engines, and fraud detection, where you need to create relationships between data and quickly query these relationships.

Graph Database is a natural solution for implementing Context-aware Services. The Graph consists of nodes representing contexts and edges connecting the nodes. The Graph structure enables you to retrieve related contexts similar to the current Context much faster compared to if a Relational Database was used.

Graph database use cases (10 examples) - Profium
Graph database uses graph structures to represent and store data for semantic queries with nodes, edges and properties and provides index-free adjacency. Graph databases are often faster for associative data sets, map more directly to the structure of object oriented applications and scale more naturally to large data sets as they do not typically require expensive join operations.

A graph database is a collection of nodes (or vertices) and edges (or relationships). A node represents an entity (for example, a person or an organization) and an edge represents a relationship between the two nodes that it connects (for example, likes or friends). Both nodes and edges may have properties associated with them.

Graph processing - SQL Server and Azure SQL Database ...
Graph databases, sometimes referred as semantic databases, have developed a lot in recent years. They have evolved into mainstream technology and have been successfully deployed across a different variety of applications. Simply put, a graph database is a purpose-built software application to store, query and modify network graphs.

Graph Database: What is It and Why It Matters for Businesses?
A graph database is a kind of database that represents data as a graph or network using nodes, edges and properties. Fitting huge amounts of connected data into a database not optimized for that purpose is a real challenge, with developers usually resorting to a relational database and joining tables, or a NoSQL database and set of foreign keys.
